## **Causes of retrograde flow in fish keratocytes**

**Prof. Dr. Josef A. Käs**  
**Universität Leipzig**

Confronting motile cells with obstacles doubling as force sensors we tested the limits of the driving actin-and-myosin-machinery. We could directly measure the force necessary to stop actin polymerization as well as the force present in the retrograde actin flow. Combined with detailed measurements of the retrograde flow velocity and specific manipulation of actin and myosin we found that actin polymerization and myosin contractility are not enough to explain the cells behavior. We show that ever-present depolymerization forces, a direct entropic consequence of actin filament recycling, are sufficient to fill this gap, even under heavy loads.
